# **A Geological Investigation of the Offshore Area along Florida's Central East Coast**

## **Annual Report to the United States Department of Interior Minerals Management Service-Year 2**

### **Introduction**

The Minerals Management Service of the US Department of Interior (MMS) and the Florida Geological Survey (FGS) have entered into a multi-year cooperative agreement (cooperative agreement # 14-35-0001-330757 / State of Florida Organization Code 3705 0204 578) with the goal of characterizing the beach nourishment potential of sands found in federal waters off the east coast of Florida. This includes federal waters out to eight miles offshore of south Brevard, Indian River, St. Lucie and Martin Counties. Figure 1 displays the area of investigation for this agreement. Year 1 tasks included the compilation of an annotated bibliography describing previously completed work in the study area, along with the implementation of an onshore push-core program to establish a baseline characterization of beach sands in the study area. Results of tasks completed during Year 1 of this investigation are summarized in "*A Geological Investigation of the Offshore Area Along Florida's Central East Coast, Annual Report to the MMS - Year 1*" Hoenstine et al., 1995), delivered to the MMS during October, 1995. FGS Open File Report #69, "*A Geological Investigation of the Offshore Area Along Florida's Central East Coast: Year 1*" (Freedenberg et al., 1995) also summarizes Year 1 results of this investigation. During October of 1995, an interim report ("*A Geological Investigation of the Offshore Area Along Florida's Central East Coast, Interim Report to the U.S. Department of Interior, Minerals Management Service*", Freedenberg et al., 1995) described a bottom sediment grab sampling program which was conducted in federal waters in the northern part of the study area. This annual report presents data collected during Year 2 and the interpretations developed to date.

This report is interim and should be viewed more as a progress report than as a report on the findings of a completed investigation.

### **Year 2 Scope of Work**

Year 2 tasks included continuation of the onshore push core program to characterize beach sediments. Eleven additional push cores were collected in Brevard County, lithologies were described and granulometric analyses were performed. Ten push cores were collected in Indian River County and were archived for future description. Year 2 also saw the acquisition, processing and preliminary interpretation of more than 500 line-miles of digitally recorded seismic data. Nineteen bottom grab samples were also collected with an Ekman dredge. All sediment samples retrieved during the grab sampling program were lithologically described and analyzed for grain size distribution.

### **Central East Coast Geology**

Various Authors have described the onshore geology of Florida's central East Coast counties. Applin et al.(1944) describes the regional subsurface stratigraphy of Florida

and southern Georgia. Brown *et al.* (1962) examined the water resources of Brevard County, while Duncan *et al.* (1994) discussed the geologic framework of the lower Floridan aquifer system in Brevard County. Davis (1997) provides a readable account of modern perspectives in Florida geology. The following account borrows from Davis.

The shorefront areas of Brevard, Indian River, St. Lucie and Martin Counties all lie on the Atlantic Coastal Plain. Mixed lithology, quartz-carbonate sand, barrier islands typify the coast of all four counties. All indurated sediments in the study area are generically assigned to the Anastasia Formation. It is likely that, while the Anastasia is generally regarded as Pleistocene in age, it also includes recently cemented (Holocene) beach rock. When examining an Anastasia specimen, there is no convenient way of knowing if the rock was cemented within the last 100 years, or is a much older relict. The Anastasia underlies all modern beach sediments in the study area.

High foredunes are locally developed on barrier islands in the area of investigation. It is these foredunes which prevent overwash and landward migration during routine tidal and acute storm events. Maintenance of these foredunes through restoration and/or stabilization is vital to maintaining beach integrity in the study area.

Sediment transport in the study area is generally to the south but littoral drift may be locally reversed forming closed circulation cells. Cell formation could be caused by variations in subsea topography which serve to focus wave energy (Mehta and Brooks, 1973). Littoral cells would cause areas of convergent sand supply supporting beach ridge growth. Accompanying these convergent sand supply areas are divergent areas where erosion predominates. Stauble and DaCosta (1987) along with Stapor and May (1983) support the existence of local littoral circulation cells, while Dean and O'Brien (1987) focus on the general southward direction of littoral transport in the study area.

Underlying the unconsolidated surface sediments and the indurated Anastasia sediments in the study area is the Neogene Hawthorn Group. The lithology of the Hawthorn group is extremely diverse, including clay, sand, limestone, silt sized dolomite and phosphorites. This lithologic variability is evidence of repeated sea-level fluctuations on an expansive shallow water shelf (Compton, 1997, p.198). Local stratigraphic studies (Hoenstine, 1984; Scott, 1986; Weedman *et al.*, 1995) suggest a late Oligocene to early Pliocene age for the Hawthrone Group Sediments.

The Eocene Ocala Limestone, along with the Avon Park Formation and Oldsmar Limestone are found below the Hawthorn Group. These sediments were laid down on a widespread shallow carbonate platform that existed from Late Cretaceous to Eocene time. The Paleocene in the area of investigation is represented by the Cedar Keys Formation, which consists of a limestone-dolomite sequence. Insufficient control makes the definitive differentiation of sub-Cedar Key sediments in the study area problematic.

### **Push Core Program**

During Year 1 of this study, FGS personnel collected seven push cores in Brevard County. Eleven additional cores were collected during July, 1996 for a total of 18 Brevard County cores. Ten additional push cores in Indian River County were also

recovered during the field portion of this year's work. These cores can be used to provide baseline characterization of beach sediments. All push cores were driven to a depth of ten feet below ground surface or until refusal. All Brevard County cores were split lengthwise, described lithologically and sampled for granulometric analyses. Figure 2 displays the locations of all cores collected in Brevard County during both the present and earlier phases of this study. Cores collected in Indian River County were archived for future description. Results of the lithologic and granulometric characteristics of push cores collected in Brevard County are summarized in Appendix A. Additional granulometric analyses were performed on those sampling intervals containing significant amounts of heavy minerals.

### **Subsurface Acoustic Profiling**

More than 500 line-miles of subsurface acoustic profile data were acquired during Year 2 of this study. All data were acquired in federal waters off of Brevard County. The seismic program consisted of 60 seven-mile-long east-west (dip) lines, one three-mile-long east-west line and two north-south (strike) lines (Fig. 3). The strike lines were 36 and 41 miles in length. Initial data collection was commenced on November 1, 1996. Data collection was halted on November 8, 1996, due to adverse sea conditions which resulted in low field productivity. The program was continued on May 5, 1997, during a period of relatively calm seas. Shooting continued until May 22, 1997. On this date, the FGS was obligated to release the chartered survey vessel so that it could commence work on another project. The data acquisition program included 14 full days, six half-days of data collection along with four standby-days when the survey vessel was unable to leave port due to unfavorable sea conditions. Production rates were significantly reduced during the half days due to marginal sea conditions. Net total time spent acquiring subsurface acoustic profile data was 17 shooting days and seven stand-by days.

All data were collected aboard the United States Geological Survey (USGS) research vessel Gilbert. The Gilbert is a purpose built, shallow draft data acquisition platform. Approximately 50 feet in length and propelled by three Hamilton jet drives, the boat is capable of making 30-35 knots in calm seas. While capable, under certain conditions, of working after sundown, the Gilbert is primarily set up for daylight operation.

Signal energy for the survey was provided by a Huntec boomer sled towed approximately 30 feet behind the research vessel. A ten station ITI streamer cable was used for signal detection. In an effort to improve signal resolution and provide repetitive imaging of the same depth point, only signals from the five adjacent geophones closest to the research vessel were activated during this shooting program. Fig. 4 illustrates the shooting geometry used in this survey.

Most previous acoustic profiling programs have relied on analog signal recording and processing. During these analog acquisition programs, the equipment operator was obligated to pick recording and final display parameters as the data was being acquired. Analog data were processed as it was recorded and immediately printed onto a paper record. No provision was made for post processing. The paper record generated during shooting was the only interpretational tool available to the interpreter.

During the present digital recording program, all field records were archived on magnetic media (Iomega Jazz drive) for long term storage. Field data can be put in a universally accepted format (SEG-Y) and transferred to a recordable CD-ROM for distribution.

An ELICS Delph II system was used for digital data recording, processing and display. The ELICS system provided an integrated platform for the digital recording and processing of subsurface acoustic profile and seismic data. Data processing parameters were chosen so as to emphasize stratigraphic differences within the sea bottom sediment.

The sled-mounted Huntec boomer signal source was towed at an approximate speed of four knots and fired four times per second. The boomer creates a bubble pulse by using a rapidly moving electromagnetically controlled plate. A capacitive discharge power supply is used to create a current which moves the plate. As the plate is manipulated, cavitation causes bubble formation. The source signal frequency is dependent on plate geometry and activation energy. The capacitive discharge power supply used in this project was set to generate 135 joules. For this survey, the boomer was configured so that most source energy had a frequency of approximately 400 hz. Field data were sampled and converted to a digital format. Signal amplitudes were recorded at a rate of 16000 times per second (this process is commonly called analog-digital conversion or adc) for a record length of 100 milliseconds (ms). This provided 1600 samples per shot record. Given the boat speed of four knots and the 250 ms shot interval, it can be calculated that the seafloor was imaged at consecutive depth imaging points of approximately 1.5 feet. Shooting parameters were chosen in consultation with the USGS.

During the processing of these data, it became apparent that sampling density was greater than that required for effective completion of the assigned task. Increasing the shot and sampling rates should also greatly decrease computer time needed for processing. Future data acquisition will use 0.5 - 1 second shot rates and 4-8 khz adc sampling rates. Record length will be increased to 200-250 ms. Using a 1 second shot rate should provide bottom image points at approximately a six foot spacing, while decreasing the adc sampling interval from 16 khz to 8 khz will decrease the maximum usable frequency ("aliasing frequency") from 8 khz to 4 khz. Collecting future data with longer record times will also make the data more useful to other investigators conducting subsurface geology studies.

Digital signal processing (dsp) allowed the precise specification of processing parameters. Data record processing was carefully controlled using selected dsp techniques including spiking deconvolution for wavelet shaping, adjusting automatic gain control (AGC) strength to preserve dynamic range and application of a digital swell filter to smooth out repetitive wave action. These techniques are much more refined than their analog equivalents. Two final displays, examples of which are included in this report, were generated for each track line. The first series of displays (Fig. 5) were scaled to emphasize the stratigraphic variations in the near-surface sediment. These displays are expanded with respect to more conventional presentations. The display is optimized to assist in the search for near-surface sands suitable for beach restoration. Maximum depth displayed on these sections is approximately 130 feet below the water

surface. The second group of displays shows the entire recorded seismic section. This display was generated for archival purposes. The data processing sequence is described in Table 1.

Preliminary interpretation of subsurface acoustic profile data is under way. Several distinct features which may be helpful in locating sand deposits have been identified. The validity of these features as predictive tools should be confirmed by the vibracore program to be conducted during Year 3 of this project. Surface ("first arrival") and near-surface variations in data amplitude may be found to have a high degree of correlation with areas of sand accumulation. In this report the term "first arrival" is used to refer to the initial and following wavelets reflected off of the water-sediment interface. These would appear within the first two milliseconds of the water-sediment interface on a display section. The first arrival is distinct from the "direct arrival" which refers to the initial energy pulse recorded directly at the geophone array without being reflected off of the water bottom. Other investigators use the term "first arrival" and "direct arrival" interchangeably to refer to what this report terms "direct arrival." Changes in amplitude and frequency of the first arrival are termed first arrival anomalies in this report. All direct arrivals, on this data set, have been filtered out during the processing sequence. They will not be visible on the displays provided with this report. In addition to variations in the first arrival signature, note was made of changes in the reflection character of the uppermost ten ms (approximately 25 feet) of the seismic section. Changes in the reflection character of the uppermost ten ms of the display are referred to as near-surface anomalies. All anomalies are tabulated in Table 2 which was used to assist in locating sites for grab sampling.

Resolution of the data is sufficiently high so that small scale facies mapping may be performed. An area of stratigraphic "onlap" has been identified off the southern portion of Brevard County. Onlap sequences are often accompanied by well developed basal transgressive sands which formed as a part of the beach pushed up before a rising sea. Such sands, if their development can be confirmed, may represent viable sources of material suitable for shoreline restoration. Figure 5 shows an excerpt from expanded profile line B-46 displaying stratigraphic onlap. This display was configured to display every tenth trace. The individual display traces are approximately 15-feet apart. Figure 6 is an excerpt from the full scale display of the same section showing every fourth trace. The interval between displayed traces is approximately six feet. Figure 7 is an excerpt from the same line processed according to conventional processing parameters. Every trace is displayed. The interval between traces is approximately 1.5 feet. Complete display records for all three presentations of line B-46 are included in Appendix C. Grab samples have not yet been collected from the onlap sequence viewed on this line.

Similarly, several areas of surface/near surface amplitude anomalies have been observed. Amplitude anomalies are caused by changes in the reflection coefficient of successive stratigraphic layers. Well defined anomalies may be observed as the sediment type changes from well compacted sand/hardground to unindurated sand/mud. Mapping amplitude changes only becomes practical with careful control of the empirically determined automatic gain control (AGC) attack/decay rates applied to the display section. This is most easily accomplished through the use of digital signal processing.

In the past, some questions have been raised about the effectiveness of subsurface acoustic profiling as a tool for the location of offshore sands. Prior studies have primarily utilized single fold analog data. Investigators did not have access to the digital signal processing tools necessary for optimum data display and interpretation. The displays presented in previous studies may not have been useful in identifying areas of sand accumulation but this is more a reflection on the processing and display parameters used than on the efficacy of the technique.

Some discussion may be appropriate as to what exactly constitutes "success" in the interpretation of subsurface acoustic profile data. Acoustic profile data are inherently ambiguous and it is unrealistic to expect a single data signature to be uniquely associated with the presence of offshore sand. In the petroleum industry, a seismic technique is considered successful if it can significantly improve the success rate beyond that success rate expected from random sampling. Most investigators would consider a 20-30% improvement significant. Subsurface acoustic profiling can produce "leads" pointing to areas that may contain accumulations of offshore sand. Not every "lead" will work out. Some of the "leads" will identify sand accumulations that are not of sufficient aerial extent, or not of sufficiently high quality to be economically viable. Other "leads" may be found to be totally without merit. For this reason, it is imperative that interpretations obtained from an acoustic profiling program be confirmed with bottom sampling and vibracore programs.

Table 2 identifies those areas which, based on preliminary interpretation of the seismic data, appear to be worthy of further investigation. Anomalies on this figure are classified according to signature.

### **Grab Sampling**

Nineteen grab samples were collected off the Brevard County coast during this phase of the cooperative agreement. This grab sampling program continued the sampling program initiated in 1995. Descriptions and analytical results of samples collected during 1995 are recorded in Freedenberg, (1995). All samples were collected during the period August 19-22, 1997, using a 24' Carolina Skiff belonging to the FGS. A six-inch Ekman dredge sampler was used for sample retrieval. At numerous sample locations, multiple attempts were necessary for the recovery of an amount of sediment sufficient for bottom characterization. During recovery at several sites (GS-1 through GS-5) the jaws of the dredge were found to be repeatedly propped open by shell material. This allowed much of the sand sized material to escape from the dredge. Repeated sampling was necessary for enough recovery to enable the granulometric analysis of sand sized material. All material recovered during successive dredging attempts was saved. The combining of samples collected in such a fashion may lead to exaggerated reporting of the coarser grain size fractions. Proposed grab sample locations were laid out on a map of the study area and assigned consecutive location numbers. Proposed grab sample locations are indicated in Appendix D. For logistical reasons, the grab sample locations were not sampled in consecutive order during implementation of the field phase of the sampling program. The original numbering system was preserved. The reader, therefore, will not find consecutive sample numbering on the grab sample location map. It will also be noted that samples from several of the proposed sampling

sites have not yet been recovered. This was due to equipment and weather conditions while in the field. These sites should be revisited during follow-up sampling in Year 3.

Lithologic and granulometric analyses of sediments collected during the grab sampling program are tabulated in Appendix B. The reporting of the percentage of fines during the first phase of the grab sampling program is reported, as detailed in Freedenberg et al., 1995, as the weight percent of sediment lost during wet sieving. The fine fraction reported in this year's grab sample program is reported as the percentage of sediment passing through a 3.5 phi sieve. This approximates the percentage fines passing through a #200 sieve as discussed in the following paragraph. Preliminary analyses of grab sample data reveal that at least two areas of previously unreported restoration quality sand appear to be present offshore of Brevard County.

The Department of Environmental Protection, Bureau of Beaches and Coastal Systems (BCS) is responsible for permitting restoration and renourishment projects in the State of Florida. Quality standards for restoration sand are defined in section 5J of Florida Administrative Code FAC 62B-41.007. According to this rule, restoration material "...shall, in general, not contain greater than 5 percent fines (passing the #200 sieve) or gravel exclusive of shell material (retained by the #4 sieve) and be free of coarse gravel or cobbles."

It should be emphasized that this rule is based only on the allowable percentages of coarse and fine materials respectively. No attempt is made to address overfill ratios or account for the existence of mixed lithology (silica-carbonate) sediments. These two issues have, so far, not been addressed in any rule promulgated by BCS.

Canaveral Shoals is a well known sand accumulation meeting these standards. A single grab sample was collected on Canaveral Shoals for calibration purposes. Additional grab samples, located on the basis of subsurface acoustic profile anomalies, reveal an extensive deposit of sand to be present 7-8 miles offshore of the Patrick AFB-Cocoa Beach area. A second sand concentration was located approximately four miles offshore of Sebastian Inlet. Both of these areas are in close proximity to beaches requiring restoration/renourishment programs. Determining the depth and lateral extent of both of these sand bodies will be necessary before any estimate of economic value can be made. An extensive vibracore program will therefore be required in order to support any estimate of economic value.

## **Executive Summary Map**

A large scale Executive Summary Map is included as Appendix D of this report. This map summarizes, on one illustration, the locations of all data and sample collection points.

Preliminary interpretation of areas judged favorable for sand accumulation are also included.

## **General Observations**

As development continues along the central Florida coast, there will be an ever increasing demand for beach restoration projects. Onshore and nearshore sources of sand suitable for beach restoration are in short supply. Offshore sand sources have potential as sources of sand for these projects but they have not yet been fully characterized. Based on preliminary work performed by the FGS, it appears that offshore sources of sand suitable for beach restoration are located off Brevard County. Further work is needed to confirm the lateral and vertical extent of these sand deposits. The availability of restoration sand off the southern portion of the study area (Indian River, St. Lucie and Martin Counties) has not yet been established. Year 3 tasks will focus on exploratory work in the southern portion of the study area, along with sand deposit delineation off Brevard County.

## **Summary and Conclusions**

- Tasks assigned to the FGS for Year 2 of the multi-year cooperative agreement have been completed.
- Approximately 500 line-miles of digitally recorded subsurface acoustic profile data has been collected. All data have been digitally processed. Representative paper displays of acoustic profile data have been included with this annual report. Complete paper displays will be provided with the final project report. Preliminary interpretation of these data has identified reflection anomalies indicating possible sand accumulations. These anomalies have been mapped. Subsurface facies suitable for sand accumulation have also been identified and mapped.
- Nineteen grab samples have been collected using an Ekman dredge. Analyses of the results obtained from granulometric analyses of grab samples reveals at least two previously unrecognized areas where beach quality sand may have accumulated.
- Eleven additional on-shore push cores have been collected in Brevard County. Ten on-shore push cores have been collected in Indian River County. All Brevard County cores have been opened. Lithologic descriptions and granulometric analyses have been performed. The Indian River County cores have been archived for analysis during Year 3 of this study.
- It is desirable to collect additional grab samples to locate additional areas of sand accumulation.
- All sand accumulations identified by grab sampling should be confirmed and have their depth and lateral extent delineated by vibracore.
- Subsurface acoustic profiling is a valid tool in the search for offshore sand accumulations.

- It is likely that the present investigation will confirm the existence of additional offshore accumulations of sand suitable for beach restoration.

## Acknowledgements

The authors would like to thank the St. Petersburg, Florida office of the United States Geological Survey for assistance in the acquisition and processing of subsurface acoustic profile data. Jack Kindinger, Dana Wiese, Richard Young and David Bennet all provided generous assistance. Thanks are also extended to the staff of the FGS for their review and suggestions during the preparation of this report.

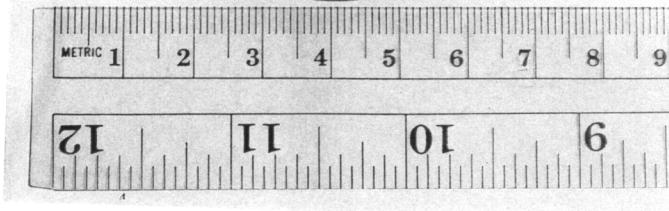

**Figure 8.** Grab Sample Photos

GS-27      Collected from Canaveral Shoals. Sample shows an abundance of sand sized material. Abundant shell debris. Canaveral Shoals has abundant sand supply and is currently being considered as an-off shore sand source.

GS-26

GS-26

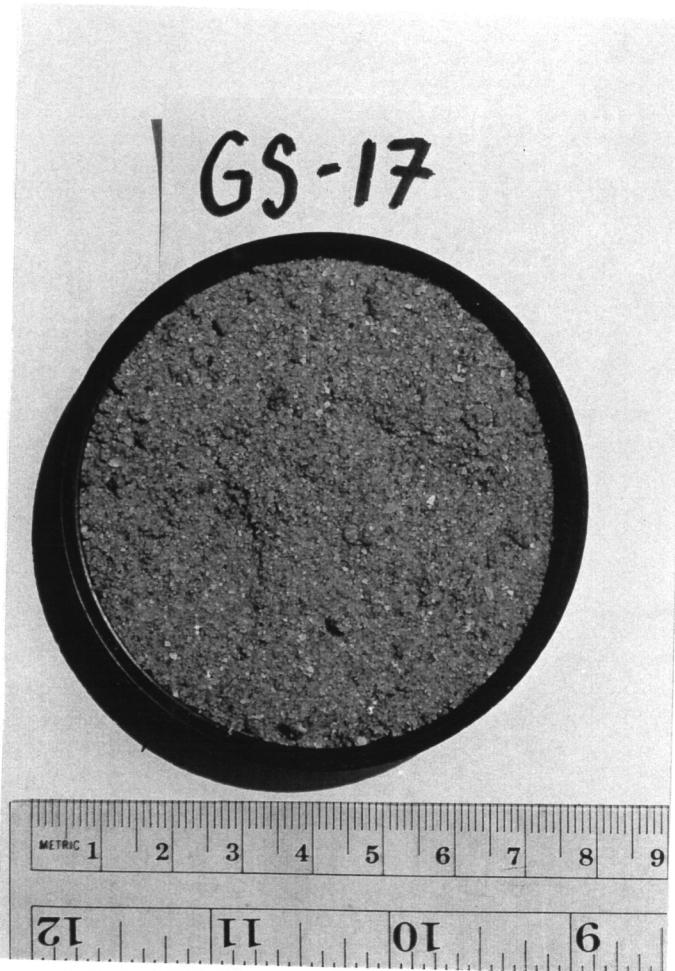

Sample contains 38.9% fine material. This sample is unsuitable for beach restoration. The fines would immediately be subject to wave dispersal causing excessive water turbidity and premature beach failure.

GS-3

GS-3

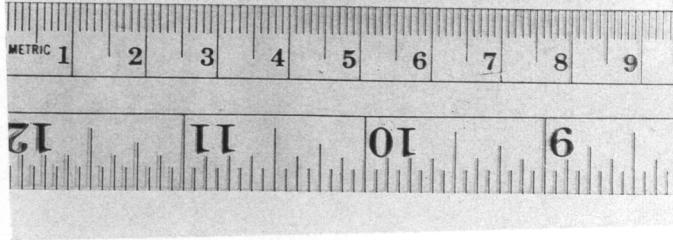

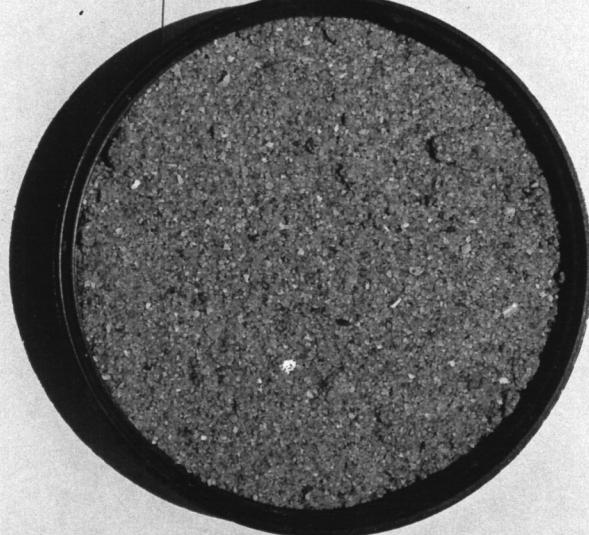

Sample collected 4.5 miles east-northeast of the mouth of Sebastian Inlet. Grain size distribution is appropriate for beach restoration. This area is previously unrecognized as a sand source.

GS-17, GS-20

The sediments in these samples show favorable characteristics for use as beach restoration material. These samples were collected approximately five and eight miles east of the Patrick AFB shoreline. This sand source was previously unrecognized. It may be contiguous with Space Coast (formerly Patrick) Shoal. Space Coast Shoal contains high quality sands but is currently believed to be of limited areal extent.

DEPTH (FT)	GEOLOGIC DESCRIPTION	LITH. USCS SYMBOL CLASS COMMENTS
1	<0-7.0') FINE TO COARSE GRAINED SAND, VERY LIGHT ORANGE TO MODERATE YELLOWISH BROWN. UNCONSOLIDATED, ANGULAR TO SUBROUNDED, MEDIUM SPHERICITY, INCLUDES SHELL FRAGMENTS.	SW (0-0.6') ACCESSORY MINERALS: 2% HEAVY MINERALS, 20% CLAY SIZED TO VERY COARSE GRAINED, ANGULAR TO SUBROUNDED SHELL DEBRIS.  (0.6-1.2') ACCESSORY MINERALS: <1% HEAVY MINERALS, 25% VERY FINE SAND TO GRAVEL SIZE, ANGULAR TO ROUNDED SHELL DEBRIS  (1.2-1.4') ACCESSORY MINERALS: 4% HEAVY MINERALS, 35% FINE TO VERY COARSE GRAINED, ANGULAR TO ROUNDED SHELL DEBRIS, INCLUDES A FEW WHOLE MOLLUSK VALVES.  (1.4-2.4') ACCESSORY MINERALS: 2% HEAVY MINERALS, 15% FINE SAND TO GRANULE SIZE, ANGULAR TO ROUNDED SHELL HASH.  (2.4-3.4') ACCESSORY MINERALS: 1% HEAVY MINERALS, 20% VERY FINE TO VERY COARSE GRAINED, ANGULAR TO ROUNDED SHELL DEBRIS, MIXED WITH TERRIGENOUS SILT AND CARBONATE MUD.  (3.4-4.2') ACCESSORY MINERALS: 1% HEAVY MINERALS, 30% FINE SAND TO GRANULE SIZE, ANGULAR TO ROUNDED SHELL DEBRIS.  (4.2-4.5') ACCESSORY MINERALS: <1% HEAVY MINERALS, 25% VERY FINE TO GRAVEL SIZE, ANGULAR TO ROUNDED SHELL DEBRIS, ABOUT 2% TERRIGENOUS SILT AND CARBONATE MUD.  (4.5-5.5') ACCESSORY MINERALS: <1% HEAVY MINERALS, 55% FINE SAND TO GRAVEL SIZE, ANGULAR TO ROUNDED SHELL DEBRIS, ABOUT 20% WHOLE MOLLUSK VALVES OF VARIOUS SIZES.  (5.5-5.7') ACCESSORY MINERALS: <1% HEAVY MINERALS, 40% FINE SAND TO GRAVEL SIZE, ANGULAR TO SUBROUNDED SHELL DEBRIS, AS ABOVE.  (5.7-6.5') ACCESSORY MINERALS: <1% HEAVY MINERALS, 50% CLAY TO GRANULE SIZE, ANGULAR TO SUBROUNDED SHELL DEBRIS, ABOUT 5% TERRIGENOUS SILT AND CARBONATE MUD.  (6.4-7.0) ACCESSORY MINERALS: <1% HEAVY MINERALS, 35% CLAY TO GRANULE SIZE, ANGULAR TO SUBROUNDED SHELL DEBRIS, ABOUT 5% TERRIGENOUS SILT AND CARBONATE MUD.
2		CORE VARIABILITY IS PRIMARILY DUE TO VARING SHELL CONTENT.
3		CLAY SIZED FRACTION IS COMPOSED OF CARBONATE MUD.

## Appendix B

Grab Sample Lithology and  
Granulometric Analyses

## BREVARD OFFSHORE GRAB SAMPLE LITHOLOGY

SAMPLE LOCATION	DESCRIPTION
GS-1	Medium gray, speckled coquina limestone about 85 percent carbonate and 15 percent quartz. Carbonate is medium sand to gravel sized; white, yellowish-brown, brownish-gray, pinkish-gray, gray and black; and subangular to rounded. Limestone is moderately well-lithified with spar cement. Carbonate grains are shell or fossilized shell and shell debris with some whole valves. Shell is predominantly bivalve or gastropod mollusk. Larger shells are encrusted with barnacles and/or bryozoans, or show signs of algal boring. A few carbonate fragments are fossilized Sabellariid worm-rock. Traces of echinoids were also present. Quartz sand is medium to coarse grained; transparent; and subangular to subrounded. This sample may be biased by loss of finer materials during sample collection.
GS-1A	Brownish-gray, speckled sand composed of about 15 percent quartz grains, and 83 percent carbonate. Carbonate is fine sand to gravel sized; white, yellowish-brown, brownish-gray, pinkish-gray, gray and black; and subangular to rounded. Where present, cement is spar. Carbonate grains are shell or fossilized shell and shell debris with some whole valves. Shell is predominantly bivalve or gastropod mollusk. Larger shells show signs of algal boring. A few carbonate fragments are fossilized Sabellariid worm-rock. Other carbonates include bryozoans, miliolids and traces of echinoids. Quartz sand is medium to coarse grained; subangular to subrounded; and transparent. Less than one percent phosphate; a trace of heavy minerals. This sample may be biased by loss of finer sands during sample collection.
GS-2	Brownish-gray, sandy shell bed with fragments of speckled coquina-limestone. Limestone comprises about 50 percent of the sample; shell about 30 percent and quartz sand about 10 percent. Carbonate is medium sand to gravel sized; white, yellowish, brown, brownish-gray, pinkish-gray, gray and black. Rock fragments vary from 0.4 cm to about 5 cm in diameter and are rounded. Shell debris is medium sand to gravel sized; subangular to rounded; and includes well-preserved whole valves and poorly preserved shell hash. Where present, cement is transparent spar. Shell hash is dominated by bivalve and gastropod mollusks, and includes fragments of echinoid spines. Both encrusting and cupuliform bryozoans are present. Quartz sand is very fine to coarse sand sized; transparent; and angular to subangular. Less than one percent heavy minerals; less than one percent phosphate.

## BREVARD OFFSHORE GRAB SAMPLE LITHOLOGY (cont.)

SAMPLE LOCATION	DESCRIPTION
GS-3	Brownish-gray, speckled sand composed of about 35 percent quartz grains, and 65 percent carbonate. Carbonate is fine sand to gravel sized; white, yellowish-brown, brownish-gray, pinkish gray, gray, green, blue and black; and subangular to rounded. Carbonate grains are rock fragments, shell, fossilized shell and shell debris with some whole valves. Shell is predominantly bivalve or gastropod mollusk. Larger shells show signs of algal boring. Other carbonates include bryozoans, miliolids and traces of echinoids. Quartz sand is medium to coarse grained; transparent; and subangular to subrounded. Less than one percent phosphate; traces of heavy minerals.
GS-4	Brownish-gray, speckled sand composed of about ten percent quartz grains, and 90 percent carbonate. Carbonate is fine sand to gravel sized; white, yellowish-brown, brownish-gray, pinkish-gray, gray, green, blue and black; and subangular to rounded. Carbonate grains are rock fragments, shell, fossilized shell and shell debris with some whole valves. Granule to gravel sized rock fragments (0.2 -4.0 cm) comprise 60 percent of the sample. Shell is predominantly bivalve or gastropod mollusk. Larger shells show signs of algal boring. Other carbonates include bryozoans, miliolids and traces of echinoids. Cement, where present, is transparent spar. Quartz fraction is bimodal: about ten percent of this is very fine to medium, subangular sand; the remainder is coarse sand to granule sized, and subrounded. This sample may be biased by loss of finer materials during sample collection.
GS-5	Brownish-gray, sandy shell bed with fragments of speckled coquina-limestone. Limestone comprises about 50 percent of the sample; shell about 30 percent and quartz sand about five percent. Larger valves and rock fragments range from three cm to about five cm in diameter. Cement is transparent spar. Shell is fresh and includes well preserved whole valves and gastropod shells. Sand sized carbonate includes medium to coarse grained, rounded shell hash and rock fragments. Both encrusting and cupuliform bryozoans are present. Fragments of fresh worm rock may indicate Sabellariid reef in this area. Quartz sand is very fine to medium sand sized, transparent, and angular to subangular. Less than one percent heavy minerals; less than one percent phosphate. This sample may be biased by loss of finer materials during sample collection.

## BREVARD OFFSHORE GRAB SAMPLE LITHOLOGY (cont.)

SAMPLE LOCATION	DESCRIPTION
GS-16	Medium light gray, speckled sand; about 70 percent quartz grains and about 30 percent carbonate. Carbonate is white, pinkish-gray, light medium gray, gray-blue and black. Carbonate grains are fresh shell, shell debris and fossilized shell, with few recognizable fossils or shells. Carbonates are subangular to rounded; and very fine sand to granule sized. A few granule sized whole mollusk valves and gastropods are present. Better preserved carbonates include benthic foraminifera, miliolids, and echinoid spines. Quartz is very fine sand to coarse grained, transparent, and angular to subrounded. The sample contains traces of heavy minerals and phosphates. Less than one percent of the sample is composed of transparent, needle-like crystals of calcium carbonate.
GS-17	Medium light gray, speckled sand; about 60 to 65 percent quartz grains and about 35 to 40 percent carbonate. Carbonate is very fine sand to granule sized; white to medium gray; and subangular to rounded. Carbonate grains are fresh shell, shell debris and fossilized shell, with few recognizable fossils or shells. A few granule sized whole mollusk valves and gastropods are present. Better preserved carbonates include benthic foraminifera, miliolids, and echinoid spines. Quartz is very fine to coarse sand, transparent, and angular to subrounded. The sample contains traces of heavy minerals and phosphates. Less than one percent of the sample is composed of transparent, needle-like crystals of calcium carbonate.
GS-18	Brownish-gray, light olive gray to medium light gray, speckled sand; about 65 percent quartz grains and about 35 percent carbonate. Carbonate is very fine sand to granule sized; white, very pale orange, yellowish-brown, and very light gray to medium gray; and subangular to rounded. Carbonate grains are shell debris, with few recognizable shells, and fragments of very pale orange to gray coquina rock. Cement is transparent spar. A few granule sized, whole mollusk shells are present. Better preserved carbonates include benthic foraminifera, miliolids, and echinoid spines. Quartz is very fine to medium sand; transparent; angular to subrounded; and well sorted. Less than one percent of the sample is composed of transparent, needle-like crystals of calcium carbonate.

## BREVARD OFFSHORE GRAB SAMPLE LITHOLOGY (cont.)

SAMPLE LOCATION	DESCRIPTION
GS-19	Light olive gray to medium light gray, clay coated, speckled sand; about 75 percent quartz grains, 20 percent carbonate, and 4 percent silt to clay sized non-calcareous fines. Carbonate is silt to granule sized; white to medium gray; and subangular to rounded. Carbonate grains are shell debris, with few recognizable shells, and fragments of gray coquina rock. Cement is transparent spar or white calcilutite. A few granule sized, whole mollusk shells are present. Better preserved carbonates include benthic foraminifera, miliolids, sponge spicules and echinoid spines. Quartz is very fine to medium sand; transparent; angular to subrounded; and well sorted. Less than one percent of the sample is composed of transparent, needle-like crystals of calcium carbonate. About one percent heavy minerals and mica.
GS-20	Brownish-gray, sand composed of about 20 percent fragments of speckled coquina limestone, 35 percent shell and shell debris, and 45 percent quartz sand. Sand sized carbonate ranges from very fine to very coarse sand; is white, pinkish-gray, yellow, orange, green, brown, blue and gray; and is subangular to rounded. Shell includes well preserved whole valves and gastropod shells. Cement is transparent spar. Recognizable fossils and shell include encrusting and cupuliform bryozoans, and echinoid fragments. Quartz is very fine to coarse sand sized; transparent; and angular to subangular. Traces of heavy minerals and mica are present.
GS-21	Light olive gray to medium light gray, clay coated, speckled sand; about 50 percent quartz grains, 45 percent carbonate, and three percent silt to clay sized, non-calcareous fines. Carbonate is white to medium gray, shell debris, with few recognizable shells. Shell is subangular to rounded; very fine to very coarse sand sized. A few granule sized, whole mollusk shells are present. Better preserved carbonates include benthic foraminifera, miliolids, sponge spicules and echinoid spines. Quartz is very fine to medium sand; transparent; angular to subangular; and well sorted. Less than one percent of the sample is composed of transparent, needle-like crystals of calcium carbonate. About one percent heavy minerals and mica.

## BREVARD OFFSHORE GRAB SAMPLE LITHOLOGY (cont.)

SAMPLE LOCATION	DESCRIPTION
GS-21-2	Light olive gray to olive-black, clay coated sand; about 80 percent quartz grains, 15 percent carbonate, and three percent terrigenous fines and organic matter. Carbonate is very fine to very coarse sand sized; white to dark gray; subangular to rounded; shell debris, with few recognizable shells and shell fragments. A few granule sized, whole mollusk shells are present. Better preserved carbonates include benthic foraminifera, miliolids, and echinoid spines. Quartz is very fine to medium sand; transparent; angular to subangular; and well sorted. Less than one percent of the sample is composed of transparent, needle-like crystals of calcium carbonate. Also contains traces of mica and heavy minerals.
GS-22	Light olive gray to olive-black, muddy sand; about 80 percent quartz grains, ten percent carbonate, and seven percent silt to clay sized, non-calcareous fines and organic matter. Shell debris is very fine to very coarse sand sized white, pinkish-gray, yellow, orange, brown, blue, gray and black; subangular to rounded; with few recognizable shells and shell fragments. A few granule sized, whole mollusk shells are present. Better preserved carbonates include benthic foraminifera, miliolids, and echinoid spines. Quartz is very fine to medium sand transparent; angular to subangular; and well sorted. Less than percent of the sample is composed of transparent, needle-like crystals of calcium carbonate. Also contains one percent mica and one to two percent heavy minerals.
GS-23	Light gray, brownish-gray, speckled sand; about 50 percent quartz grains, and 50 percent carbonate. Carbonate is microcrystalline to very coarse sand sized; white, yellow, orange, brownish-gray and black; and subangular to rounded. Carbonate grains are shell debris, with few recognizable shells, and fragments of gray or brown coquina rock. Cement is transparent spar or white calcilutite. A few granule sized, whole mollusk shells are present. Other carbonates include cupuliform bryozoa and echinoid spines. Quartz is very fine to coarse sand; transparent; angular to subrounded; and well sorted. Less than one percent heavy minerals and mica.

## BREVARD OFFSHORE GRAB SAMPLE LITHOLOGY (cont.)

SAMPLE LOCATION	DESCRIPTION
GS-24	Brownish-gray to olive gray, clay coated, speckled sand composed of about 75 percent quartz grains, 20 percent carbonate, and five percent white, silt to clay sized calcilutite, and non-calcareous olive clay. Shell debris is microcrystalline to very coarse sand sized; white, pinkish-gray, yellow, orange, brown, blue, green, gray and black; subangular to rounded with few recognizable shells and shell fragments. A few granule sized, whole mollusk shells are present. Better preserved carbonates include benthic foraminifera, miliolids, and echinoid spines. Quartz is very fine to medium sand; transparent; angular to subangular; and well sorted. A trace of transparent, needle-like crystals of calcium carbonate. Also contains one percent mica.
GS-25	Brownish-gray to olive gray, clay coated, speckled sand composed of about 30 percent quartz grains, 65 percent carbonate, and five percent white, silt to clay sized calcilutite, and non-calcareous olive clay. Shell debris is microcrystalline to very coarse sand sized; white, pinkish-gray, yellow, orange, red, brown, blue, green, gray and black, subangular to rounded; with few recognizable shells and shell fragments. A few granule sized, whole mollusk shells are present. Other carbonates include benthic foraminifera, miliolids, coral fragments and echinoid spines. Quartz is very fine to coarse sand; transparent; angular to subangular; and well sorted. Also contains one percent mica.
GS-26	Light olive gray to olive-black, muddy fine sand; about 68 percent quartz grains, 25 percent carbonate, and five percent silt to clay sized, noncalcareous fines and organic matter. Shell debris is very fine to very coarse sand sized; white, pinkish-gray, yellow, orange, brown, blue, gray and black; subangular to rounded; with few recognizable shells and shell fragments. A few granule sized, whole mollusk shells are present. Better preserved carbonates include benthic foraminifera, miliolids, and echinoid spines. Quartz is very fine to medium sand; transparent; angular to subangular; and well sorted. Less than one percent of the sample is composed of transparent, needlelike crystals of calcium carbonate. Also one to two percent mica and less than one percent heavy minerals.

## BREVARD OFFSHORE GRAB SAMPLE LITHOLOGY (cont.)

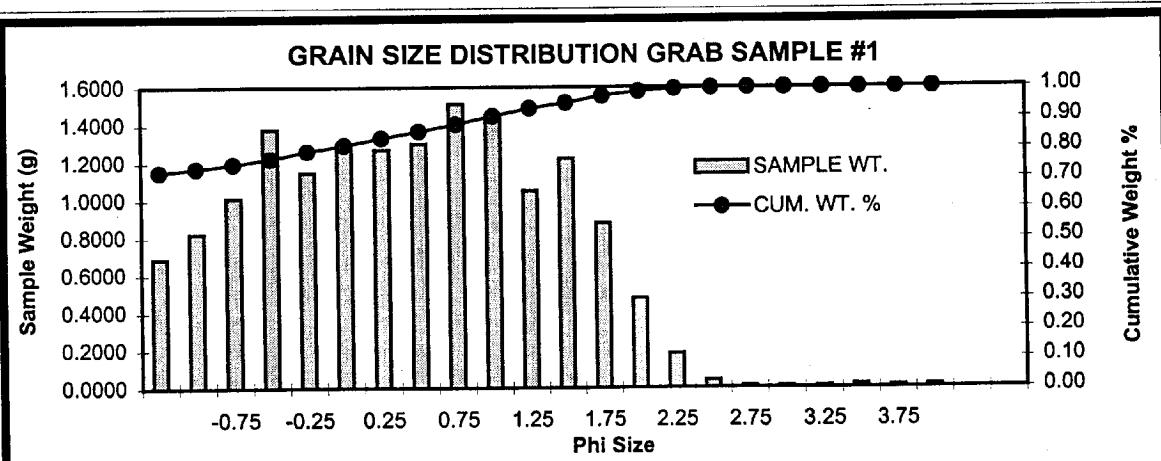

SAMPLE LOCATION	DESCRIPTION
GS-27	Brownish-gray, speckled sand composed of about 60 percent quartz grains, and 40 percent carbonate. Carbonate is fine sand to gravel sized; white, yellowish-brown, brownish-gray, pinkish-gray, gray, green, blue and black; and subangular to rounded. Carbonate grains are rock fragments, shell, fossilized shell and shell debris with some gravel sized whole valves. Shell is predominantly bivalve or gastropod mollusk. Larger shell show signs of algal boring. Other carbonates include cupuliform bryozoans, and echinoid spines. Quartz is very fine to coarse sand sized; transparent; and subangular to subrounded.
